Application for United States Letters Patent

To all whom it may concern:

Be it known that

Christos J. Petropoulos

have invented certain new and useful improvements in

PRODUCTION OF INFECTIOUS HEPADNAVIRUS PARTICLES CONTAINING FOAMY RETROVIRUS ENVELOPE PROTEINS AND METHODS OF USING THE SAME

of which the following is a full, clear and exact description.

PRODUCTION OF INFECTIOUS HEPADNAVIRUS PARTICLES CONTAINING FOAMY RETROVIRUS ENVELOPE PROTEINS AND METHODS OF USING THE SAME

application, various publications Throughout this are referenced by author and date within the text. Full citations for these publications may be found listed alphabetically at the end of the specification immediately All patents, patent applications preceding the claims. and publications cited herein, whether supra or infra, are hereby incorporated by reference in their entirety. disclosures of these publications in their entireties are hereby incorporated by reference into this application in order to more fully describe the state of the art as known to those skilled therein as of the date of the invention described and claimed herein.

Background of the Invention

HBV replication

5

10

25

30

Hepatitis B virus (HBV) particles can be produced by the transient expression of molecular clones of full-length cultures and hepatocyte primary DNA in Virus particles produced in this hepatoma cell lines. manner resemble the infectious virions (Dane particles) of HBV-infected individuals and their infectivity has been demonstrated in chimpanzees. Unfortunately, HBV particles produced in such in vitro cell systems do not productively infect hepatic cell lines maintained in vitro (e.g. HepG2 This limitation has restricted the study of HBV cells). replication and the development of antiviral

Similarly, the inablility to infect target host cells with HBV particles generated with HBV resistance test vectors is an obstacle in the development of a two cell drug susceptibility assay for HBV as described in U.S. Patent No. 6,242,187. This block to infection is not understood and may reflect the absence of functional HBV receptors on the surface of available hepatic cell lines, although data supporting other possible explanations have been presented The HBV receptor(s) has yet not been identified.

5

is desired, therefore, are means and methods of particles capable infecting produce hepadnavirus lines maintained in vitro. What is cell hepatic desired are means and methods to produce hepadnavirus particles which can be used to conduct drug susceptibility resistance testing, viral fitness assays, genotypic analysis using a host and target cell, i.e. a two cell in vitro system.

Summary of the Invention

Accordingly it is an object of the invention to provide a method for the production of hepadnavirus particles capable of infecting hepatic cell lines maintained in vitro.

25

A further object of the invention is to provide a method of using infectious hepadnavirus particles to conduct drug susceptibility and resistance testing using a two cell system.

30

Another object of the invention is to provide a method of using infectious hepadnavirus particles to conduct in

vitro drug susceptibility and resistance testing wherein a detectable signal is produced to measure infectivity.

A further object of the invention is to provide in vitro drug susceptibility and resistance testing as described above using the infectious hepadnavirus particles comprising a patient-derived segment.

A further object of the invention is to provide an in vitro method of using infectious hepadnavirus particles to determine replication capacity for patient's hepadnavirus.

Yet another object of the invention is to provide a method of identifying a mutation in a hepadnavirus which confers resistance to a compound which inhibits hepadnavirus replication.

These and other objects may be achieved by the present invention by: producing a hepadnavirus virion that is infectious in vitro which comprises: (a) introducing into a cell (i) a hepadnavirus genome expression vector and (ii) a foamy retrovirus envelope expression vector which comprises a nucleic acid encoding at least a fragment of a foamy virus envelope protein, and (b) culturing the cell thereby producing hepadnavirus virions comprising at least a fragment of a foamy virus envelope protein, wherein the hepadnavirus virions are infectious in vitro.

Detailed Description of the Invention

5

This invention provides: a method for producing a hepadnavirus virion that is infectious in vitro which comprises:

cell introducing into a (i) а hepadnavirus (a) and (ii) foamy expression vector а 10 genome which expression vector retrovirus envelope comprises a nucleic acid encoding at least a fragment of a foamy virus envelope protein; and

cell thereby producing culturing the 15 (b) at least hepadnavirus virions comprising envelope protein, of foamy virus wherein the hepadnavirus virions are infectious in vitro.

20

A further embodiment, the invention provides the above method wherein the hepadnavirus genome expression vector lacks a nucleic acid encoding a hepadnavirus envelope protein.

25

30

A further embodiment, the invention provides the above method, wherein the hepadnavirus genome expression vector comprises at least one gene from a hepadnavirus genome selected from the group consisting of: a wood chuck hepatitis virus (WHV) genome, a ground squirrel hepatitis (GSHV) virus genome, a duck hepatitis B virus (DHBV) genome, a snow goose hepatitis virus (SGHV) genome, and a human hepatitis B virus (HBV) genome.

30

10

5

A further embodiment, the invention provides the above method, wherein the hepadnavirus genome expression vector comprises a gene from a human hepatitis B virus (HBV) genome.

A further embodiment, the invention provides the above method, wherein the hepadnavirus genome expression vector further comprises an exogenous regulatory element.

A further embodiment, the invention provides the above method, wherein the exogenous regulatory element is a human cytomegalovirus immediate-early gene promoter/enhancer (CMV-IE).

A further embodiment, the invention provides the above method, wherein the foamy retrovirus envelope expression vector comprises at least a fragment of a gene from a foamy virus genome selected from the group consisting of: a siman foamy virus (SFV) genome, a feline foamy virus (FFV) genome, a bovine foamy virus (BFV) genome, a sea lion foamy virus (SLFV) genome, a hampster foamy virus (HaFV) genome, and a human foamy virus (HFV) genome.

A further embodiment, the invention provides the above method, wherein the gene encodes an envelope protein or a fragment thereof.

A further embodiment, the invention provides the above method, wherein the foamy retrovirus envelope expression vector comprises a gene or a fragment of a gene from a human foamy virus (HFV) genome.

A further embodiment, the invention provides the above method, wherein the gene or the fragment of the gene from a human foamy virus (HFV) genome encodes the gp130env envelope gene product or a fragment thereof.

5

A further embodiment, the invention provides the above method, wherein the cell is a mammalian cell.

A further embodiment, the invention provides the above method, wherein the cell is an avian cell.

A further embodiment, the invention provides the above method, wherein the avian cell avian hepacyte.

A further embodiment, the invention provides the above method, wherein the mammalian cell is a human cell.

A further embodiment, the invention provides the above method, wherein the human cell is a human embryonic kidney cell.

A further embodiment, the invention provides the above method, wherein the mammalian cell is a 293 cell.

A further embodiment, the invention provides the above method, wherein the human cell is a human hepatoma cell.

A further embodiment, the invention provides the above method, wherein the human hepatoma cell is an HepG2 cell or an Huh7 cell.

30

25

In another embodiment, the invention provides a hepadnavirus virion that is infectious in vitro which

comprises at least a fragment of a foamy retrovirus envelope protein.

In another embodiment, the invention provides a hepadnavirus virion wherein the hepadnavirus virion is isolated.

Ιn another embodiment, the invention provides а wherein the hepadnavirus virion foamy retrovirus is selected from the group consisting of: a siman foamy virus (SFV), a feline foamy virus (FFV), a bovine foamy virus (BFV), a sea lion foamy virus (SLFV), a hampster foamy virus (HaFV), and a human foamy virus (HFV).

embodiment, the invention provides Ιn another hepadnavirus wherein the virion hepadnavirus virion chimeric envelope protein which consists comprises a essentially of (i) a hepatitis B virus envelope protein domain and (ii) a foamy virus envelope protein domain.

In another embodiment, the invention provides a hepadnavirus virion wherein the hepadnavirus virion further comprises a nucleic acid isolated from a subject infected by a hepadnavirus.

In another embodiment, the invention provides a hepadnavirus virion wherein the nucleic acid isolated from the subject infected by hepadnavirus encodes a reverse transcriptase.

25

5

10

GOMENT OFFI

10

In another embodiment, the invention provides a hepadnavirus virion wherein the hepadnavirus further comprises an indicator nucleic acid.

5 In another embodiment, the invention provides a cell comprising the hepadnavirus virion.

In another embodiment, the invention provides a cell comprising the hepadnavirus virion, wherein the cell is a mammalian cell.

In another embodiment, the invention provides a cell comprising the hepadnavirus virion, wherein the mammalian cell is a 293 cell.

In another embodiment, the invention provides a cell comprising the hepadnavirus virion, wherein the mammalian cell is a human cell.

In another embodiment, the invention provides a cell comprising the hepadnavirus virion, wherein the human cell is a human kidney cell.

In another embodiment, the invention provides a cell comprising the hepadnavirus virion, wherein the human cell is a human hepatoma cell.

In another embodiment, the invention provides a method for determining susceptibility for an anti-hepadnavirus drug which comprises:

- 30 (a) introducing into a first cell:
 - (i) a hepadnavirus genome expression vector;

- (ii) a nucleic acid encoding at least a fragment of a foamy retrovirus envelope protein, and
- 5 (iii) an indicator nucleic acid;
- (b) culturing the first cell from step (a) so as to produce hepadnavirus virions;
- 10 (c) admixing the hepadnavirus virions produced in step (b) with a second cell, wherein the anti-hepadnavirus drug is present with the first cell or the second cell, or with the first and second cell,

(d) measuring the amount of detectable signal produced by the indicator nucleic acid in the second cell, wherein the amount of detectable signal produced is dependent upon hepadnavirus virion infection of the second cell; and

20

(e) comparing the amount of signal measured in step (d) with the amount signal measured in the absence of the drug, wherein a decrease in the amount of signal measured in the presence of the drug indicates susceptibility to the drug and wherein no change in signal measured or an increase in the amount of signal measured in the presence of the drug indicates resistance to the drug.

25

In another embodiment, the invention provides the above method for determining susceptibility, wherein the hepadnavirus genome expression vector of step (a) further comprises a nucleic acid derived from a patient infected with hepadnavirus.

In another embodiment, the invention provides the above method for determining susceptibility, wherein the nucleic acid derived from a patient infected with hepadnavirus comprises at least a fragment of a human hepatitis B virus (HBV) gene.

In another embodiment, the invention provides the above method for determining susceptibility, wherein the gene is an HBV P gene, an HCV C gene, an HBV X gene or an HBV S gene.

In another embodiment, the invention provides the above method for determining susceptibility, wherein the nucleic acid derived from a patient infected with hepadnavirus encodes reverse transcriptase.

In another embodiment, the invention provides the above method for determining susceptibility, wherein the second cell is a mammalian cell

In another embodiment, the invention provides the above method for determining susceptibility,, wherein the second cell is an avian cell.

30

25

In another embodiment, the invention provides the above method for determining susceptibility, wherein the avian cell avian hepacyte.

In another embodiment, the invention provides the above method for determining susceptibility, wherein the mammalian cell is a human cell.

5

In another embodiment, the invention provides the above method for determining susceptibility,, wherein the human cell is a human embryonic kidney cell.

10

In another embodiment, the invention provides the above method for determining susceptibility, wherein the mammalian cell is a 293 cell.

15

In another embodiment, the invention provides the above method for determining susceptibility, wherein the human cell is a human hepatoma cell.

20

In another embodiment, the invention provides the above method for determining susceptibility,, wherein the human hepatoma cell is an HepG2 cell or an Huh7 cell.

25

In another embodiment, the invention provides the above method for determining susceptibility,, wherein the foamy retrovirus is selected from the group consisting of: a siman foamy virus (SFV), a feline foamy virus (FFV), a bovine foamy virus (BFV), a sea lion foamy virus (SLFV), a hampster foamy virus (HaFV), and a human foamy virus (HFV).

In another embodiment, the invention provides the above method for determining susceptibility, wherein the nucleic acid of step (a) (i) encodes a gp130env envelope protein.

5

10

30

In another embodiment, the invention provides the above method for determining susceptibility, wherein the nucleic acid of step (a) (i) encodes a protein chimeric envelope which (i) a hepatitis B virus envelope essentially of protein domain and (ii) a foamy virus envelope protein domain.

In another embodiment, the invention provides the above method for determining susceptibility, wherein the second cell expresses on its surface a protein which binds human foamy virus envelope protein.

In a further embodiment the invention provides a method for determining replication capacity of a hepadnavirus from an infected patient comprising:

- (a) introducing into a first cell:
- (i) a hepadnavirus genome expression vector;
 - (ii) a nucleic acid encoding at least a fragment of a foamy retrovirus envelope protein, and
 - (iii) an indicator nucleic acid;

- (b) culturing the cell from (a) so as to produce hepadnavirus virions;
- (c) admixing the hepadnavirus virions produced in step (b) with a second cell,
- (d) measuring the amount of detectable signal produced by the indicator nucleic acid in the second cell, wherein the amount of detectable signal produced is dependent upon hepadnavirus virion infection of the second cell;
- (e) normalizing the measurement of step (d);
 and
- comparing the normalized measurement of (f) step (e) with the amount signal measured when steps (a) through (d) are carried 20 control out with а reference hepadnavirus, wherein an increase in signal compared to the control indicates an increased replication capacity and a decrease in signal measured compared to 25 control indicates а decreased the replication capacity of the hepadnavirus from the infected patient.
- 30 In a further embodiment the invention provides a method for determining susceptibility for an anti-hepadnavirus drug which comprises:

(a)	introducing	into	а	cell

- (i) a hepadnavirus genome
 expression vector;
- 5 (ii) a nucleic acid encoding at least a fragment of a foamy retrovirus envelope protein, and
- 10 (iii) an indicator nucleic acid;
 - (b) culturing the cell from step (a);
 - (c) contacting the cell with the antihepadnavirus drug;
 - (d) measuring the amount of detectable signal produced by the indicator nucleic acid in the cell; and
 - (e) comparing the amount signal of measured in step (d) with the amount. signal measured in the absence of the decrease the drug, wherein а in amount of signal measured in the presence of the drug indicates susceptibility the drug and to wherein no change in signal measured the increase in amount or an signal measured in the presence of the drug indicates resistance to the drug.

In a further embodiment the invention provides the above method, wherein the hepadnavirus genome expression vector of step (a) further comprises a nucleic acid derived from a patient infected with hepadnavirus.

5

In a further embodiment the invention provides the above method, wherein the nucleic acid derived from a patient infected with hepadnavirus comprises at least a fragment of a human hepatitis B virus (HBV) gene.

In a further embodiment the invention provides the above method, wherein the gene is an HBV P gene or an HBV C gene.

In a further embodiment the invention provides the above method, method for identifying a mutation in a hepadnavirus nucleic acid that confers resistance to an anti-hepadnavirus drug which comprises:

20

(a) sequencing the hepadnavirus nucleic acid prior to use of the anti-hepadnavirus drug;

25

(b) measuring susceptibility of the hepadnavirus sequenced in step(a) to the drug according to the method of claim 50;

30

(c) exposing the hepadnavirus to the drug so as to produce a decrease in the susceptibility of the hepadnavirus to the drug measured in step (b);

(d)	comparing		the		sequ	ence
	determined	in	step	(a)	with	the
	sequence	of	the	hep	adnav	irus
	following	the	expo	sure	e to	the
	drug of	step	o. (c)	sc	o as	to
	identify	a	mutat.	ion	in	the
	hepadnavir	us	nuclei	ic a	cid	that
	confers re	sist	ance	to t	the a	nti-
	hepadnavir	us c	lrug.		•	

In a further embodiment the invention provides the measuring method, wherein step (b) above susceptibility 15 comprises measuring the hepadnavirus sequenced in step (a) the anti-hepadnavirus drug using a two cell assay.

In a preferred embodiment of the invention, the
invention provides a method for the production
of infectious Human Hepatitis B Virus (HBV)
particles by pseudotyping HBV virions using
envelope proteins derived from the Human Foamy
Virus (HFV).

25

30

5

10

In yet another embodiment of the invention, a method is provided for the production of infectious HBV particles by pseudotyping using chimeric envelope proteins derived from specific functional domains of the HBV and HFV envelope proteins.

Further embodiments of the invention include the production of other various hepadnaviruses, using human foamy virus envelope proteins or envelope proteins derived from 5 specific functional domains of hepadnavirus human foamy virus envelope proteins. and Examples of other hepadnaviruses include, but not restricted to, woodchuck hepatitis virus (WHV), ground squirrel hepatitis (GSHV), duck hepatitis B virus (DHBV), snow 10 hepatitis virus (SGHV), and other less-well documented hepadnaviruses isolated from cats, rodents, marsupials and birds.

15 Other embodiments of the invention include the hepadnaviruses using various production of envelope proteins virus or other foamy proteins derived from chimeric envelope domains of hepadnavirus specific functional foamy virus 20 various other envelope and Examples of other foamy viruses proteins. (also referred to as spumaviruses) but are not restricted to, simian foamy virus (SFV), feline foamy virus (FFV), bovine foamy virus (BFV), sea lion foamy virus (SLFV), and 25 hamster foamy virus (HaFV).

invention include the Other embodiments of the various production **HBV** other of or using retrovirus hepadnaviruses proteins or chimeric envelope proteins derived domains specific functional from retrovirus virus envelope hepadnavirus and

10

25

30

proteins. Examples of other retroviruses include, but are not restricted to:

- (i) Type B retroviruses (mouse mammary tumor
 virus);
- (ii) Mammalian C-type retroviruses (ecotropic murine leukemia virus, amphotropic murine leukemia virus, gibbon ape leukemia virus, feline leukemia virus, subgroup B); (iii) Avian sarcoma/leukosis retroviruses (subgroups A, B/E, D);
- (iv) Type D retroviruses (Mason-Pfizer monkey virus, simian retrovirus 1 and 2);
- (v) Human T cell leukemi viruses (type I and II) and bovine leukemia virus;
- (vi) Lentiviruses (human immunodeficiency
 virus type 1 and 2, equine infectious anemia
 virus, maedi/visna virus);
- (vii) Fish retroviruses (walleye pike leukemia
 and sarcoma viruses, snakehead fish
 retrovirus);
 - (viii) Drosophila retrovirus (gypsy).

Other embodiments of the invention include production of hepadnaviruses using envelope proteins derived from other various enveloped viruses or chimeric envelope proteins derived specific functional domains of the from envelope proteins of hepadnaviruses and other various enveloped viruses. Examples of other enveloped enveloped viruses include, but are not restricted to, togaviruses, flaviviruses, coronaviruses, rhabdoviruses, filoviruses, paramyxoviruses, orthoviruses, bunyaviruses,

arenaviruses, herpesviruses, poxviruses, iridovirusesand rotaviruses.

In another embodiment, the invention provides a method for measuring the replication of HBV, and the replication of various other hepadnaviruses.

In another embodiment, the invention provides a method for measuring the susceptibility of HBV and other hepadnaviruses to drugs that inhibit HBV reverse transcriptase, and the reverse transcriptases of other hepadnaviruses.

In another embodiment, the invention provides a method for identifying new and/or additional inhibitors of HBV reverse transcriptase, and the reverse transcriptases of other hepadnaviruses.

The means and methods for measuring HBV replication of the present invention can be applied to the identification of novel inhibitors of HBV replication including, but not limited to, cccDNA formation, virion assembly, and egress from the cell.

In another embodiment, the invention provides a method for identifying mutations in the HBV P gene that alter the susceptibility of HBV to reverse transcriptase inhibitors.

10 COMMON THE CONTROL TO CONTROL

5

25

20

The means and methods of the present invention for identifying mutations that alter susceptibility to reverse transcriptase inhibitors can be adapted to other steps in HBV replication, including, but not limited to, cccDNA formation, virion assembly and egress from the cell.

In another embodiment, the invention provides a method for identifying mutations in the HBV P gene that alter the replicative capacity, or "fitness" of HBV.

The means and methods of the present invention for identifying HBV P gene mutations that alter replicative capacity can be applied to the identification of mutations in other HBV genes (core (C), surface (S), and transactivation (X)) that alter HBV replicative capacity.

In another embodiment, the invention provides a method for using measurements of HBV drug susceptibility to guide the antiviral treatment of individuals infected with HBV.

In another embodiment, the invention provides a method for using replicative capacity measurements to guide the treatment of individuals failing anti-HBV drug treatment.

The embodiments of the present invention are achieved by using envelope proteins derived

25

5

10

15

20

from a foamy retrovirus to to produce pseudotyped hepadnavirus virions.

Foamy virus (Spumavirus) replication

The replication pathways of hepadnaviruses (which includes HBV) and retroviruses are similar in that both package a genomic length RNA and utilize reverse transcriptase (RT) to generate a double stranded (ds) DNA that serves as the template for transcription of viral genes in infected cells. Foamy viruses (also referred to as spumaviruses) comprise an atypical genus within the retrovirus group in that several their replication aspects of pathway from that of all other retrovirus distinct Notably, these unusual aspects of the replication closelv resemble foamv virus features of hepdnavirus replication, including HBV, and could reflect a common evolutionary link between hepadnaviruses and foamy viruses. Foamy viruses have been reported to infect a variety of cell types from а variety mammalian and avian species, suggesting that foamy virus receptors represent ubiquitously expressed cell surface proteins.

<u>Similarities Between Hepadnavirus and Foamy Virus</u> Replication

Both hepadnaviruses and retroviruses utilize RT during replication. During hepadnavirus replication, the conversion of a packaged single stranded pre-genomic RNA transcript to

10 CAMBELLA CENTRAL

5

25

15

20

10

25

30

double stranded genomic DNA by RT takes place before virus particles enter new host cells. Conversely, during retrovirus replication, this step occurs after the virus entry step. Recent studies indicate that unlike all other known retroviruses, an estimated 10-15% foamy virus particles contain genomic length double stranded DNA (Yu et al., (1996), "Human Foamy Virus Replication-a Pathway Distinct from That of Retroviruses and Hepadnaviruses", Science 271: 1579-1582; Yu et al., (1999), "Evidence That the Human Foamy Virus Genome is DNA", J. Virol. 70: 1250-1254). In this group retroviruses, significant amounts reverse transcription occurs before virus particles infect new cells, thus resembling the RT step in hepadnavirus replication.

In newly infected cells, both hepadnaviruses and retroviruses produce large amounts of viral core protein. For hepadnaviruses this is the C protein and for retroviruses it includes the Gag polyprotein consisting of domains that comprise the matrix (MA), capsid (CA) nucleocapsid (NC) proteins. In hepadnaviruses foamy viruses the core proteins and transiently localize within the nucleus. The novo synthesized core proteins de polyprotein) of all other known retroviruses are restricted to the cytoplasm of infected The NC domain of all retrovirus Gag cells. polyproteins, except the foamy contains a highly conserved cysteine-histidine

10

20⊨

25

30

(Cys-His) motif that plays an essential role in the binding of NC to retrovirus genomic RNA and packaging. Berkowitz, R. et al. 1996. RNA packaging. Curr. Top. Microbiol. Immunol. 214:177-218. The NC domain of foamy virus Gag the Cys-His polyproteins lack motif, contains several regions rich in glycine and arginine (Gly-Arg). Schliephake, A.W., et al. 1994. Nuclear localization of foamy virus Gag precursor protein. J. Virol. 68:4946-4954. Yu, S.F., et al. 1996. The carboxyl terminus of the human foamy virus Gag protein contains separable nucleic acid binding and nuclear transport domains. J. Virol. 70:8255-8262. One of these regions was shown to function as a nuclear localization signal. Analogous Gly-Arg motifs exist in the hepadnavirus core (C proteins and are likely to play important roles in RNA packaging and nuclear localization of the C protein Hatton, T., et al. 1992. RNA- and DNA-binding activities in hepatitis B virus capsid protein: a model for their roles in virus replication. J. Virol. 66:5232-5241. Nassal, M. 1992, The argininerich domain of the hepatitis B virus core for is required pergenome protein encapsidation and productive viral positivesynthesis but for virus strand DNA not assembly. J. Virol. 66:4107-4116.

All of the known retroviruses, except the foamy viruses, express their pol genes (RT and integrase (IN) proteins) as Gag-Pol

5

10

25

30

Prior to, and during virion formation both hepadnaviruses and retroviruses concentrate specific envelope proteins within a specific host cell membrane compartment that serves as the source of virus envelope membrane. case of hepadnaviruses these are the three surface proteins encoded by the S gene (large, middle and small S) and for retroviruses they are the surface (SU) and transmembrane (TM) proteins encoded by the envelope (env) gene. Both hepadnavirus S proteins and foamy virus TM proteins are reported to contain sorting motifs that localize these proteins within the ER membrane compartment Goepfer, P.A., et al. A sorting motif localizes the foamy 1997. virus glycoprotein to the endoplasmic J. Virol. 71:778-784, T. Kamimura reticulum. et al., and P. Roingeard, 1990. For many, if not all known retroviruses, excluding the expression foamy viruses, env protein is dispensible for the egress of virions from the cell (albeit env deficient particles are not In contrast, the egress of infectious).

10

25

30

infectious foamy virus particles from the cell is dependent on env gene expression (4 and Similarly, the assembly of infectious hepadnavirus virions is dependent expression of S gene products, and more budding requires appropriate specifically expression of the large S protein. Bruss & Ganum 1991 from table.

The features shared by foamy viruses and hepadnaviruses are summarized in Table 1.

In the case of the human hepatitis B virus, particles produced by HBV transient transfection of cultured cells are infectious in vivo, but not in vitro. The block to infection may be due to the absence of an appropriate HBV receptor on the cell surface. In contrast, human foamy virus (HFV) has a very broad host range and is capable infecting a wide variety of cell lines. This suggests that the HFV receptor may ubiquitously expressed cell surface protein.

HBV and HFV replication pathways have several similar features with respect to virion assembly and budding. The invention describes the means and methods to exploit similarities the replication pathways between HBV and hepadnavirus, such as foamy retrovirus, such as HFV in order to circumvent obstacles that restrict hepadnavirus infection culture systems. In a preferred in cell

25

30

embodiment, HFV envelope proteins, or chimeric envelope proteins containing specific functional domains of the HBV and HFV envelope proteins, can be used to generate HBV particles that are capable of using the human foamy virus receptor to enter a wide variety of cell types.

"hepadnavirus As used herein, expression vector" refers to a vector(s) that at least а fragment of. comprises hepadnavirus genome and is capable of transcription of the transient hepadnavirus and hepadnavirus production RNA protein following introduction into appropriate an cell line.

retrovirus envelope Αn "foamy expression vector" refers to a vector that comprises at а least fragment οf foamy retrovirus envelope gene and is capable of transiently producing a foamy retrovirus envelope protein following introduction into an appropriate cell line.

"indicator nucleic acid" refers nucleic acid that either directly or through a gives rise to a measurable reaction noticeable aspect or detectable signal, e.g. a color or light of a measurable wavelength or in the case of DNA or RNA used as an indicator a change or generation of a specific DNA or structure. Preferred examples RNA an

25

30

indicator gene is the E. coli lacZ gene which encodes beta-galactosidase, the luc gene which encodes luciferase either from, for example, Photonis pyralis (the firefly) or Renilla reniformis (the sea pansy), the E. coli phoA gene which encodes alkaline phosphatase, green fluorescent protein and the bacterial CAT gene chloramphenicol which encodes acetyltransferase. Additional preferred examples of an indicator gene are secreted proteins or cell surface proteins that such readily measured by assay, as or fluorescent (RIA), radioimmunoassay activated cell sorting (FACS), including, example, growth factors, cytokines and cell surface antigens (e.g. growth hormone, Il-2 or "Indicator CD4, respectively). gene" is understood to also include a selection gene, also referred to as a selectable marker. Examples of suitable selectable markers for mammalian cells are dihydrofolate reductase kinase, hygromycin, thymidine (DHFR), neomycin, zeocin or E. coli gpt. In the case of the foregoing examples of indicator genes, indicator gene and the patient-derived the i.e. distinct seament are discrete, cases a patientseparate genes. Ιn some mav also be used derived segment as an such embodiment in indicator gene. Ιn one which the patient-derived segment corresponds to more than one viral gene which is the target of an anti-viral, one of said viral genes may also serve as the indicator gene.

The indicator nucleic acid or indicator gene may be "functional" or "non-functional" as described in U.S. Patent No. 6,242,187.

5

10

25

30

"hepadnavirus indicator vector" Α or "indicator gene viral vector" refers to a DNA that contains elements the vector hepadnavirus genome and an indicator gene, such as firefly luciferase and is capable of transient transcription of an RNA. The RNA contains the signals/elements required for packaging of the RNA into hepadnavirus virions for reverse transcription of the transcript by the hepadnavirus polymerase and for the expression of the indicator gene,

A "packaging host cell" or "first cell" refers to a cell that can support transient expression of the hepadnavirus genomic and foamy retrovirus envelope expression vectors.

A "target cell" or "second cell" refers to cells foamy retrovirus that express а capable of are supporting receptor and hepadnavirus replication once foamy retrovirus pseudotyped hepadnavirus virions have entered the cell via the foamy retrovirus receptor. What is meant by "foamy retrovirus pseudotyped hepadnavirus virions" are hepadnavirus or more proteins containing one virions derived from a foamy retrovirus.

As herein, "patient-derived segment" used encompasses nucleic acid segments derived from and various animal species. species include, but are not limited chimpanzees, horses, cattles, cats and dogs.

Patient-derived segments can also be incorporated into be described vectors, such as the hepadnavirus expression vector using any of several alternative cloning techniques. For example, cloning via the introduction of class II restriction sites into both the plasmid backbone and the patient-derived segments or by uracil DNA glycosylase primer cloning or a method of recombination or seamless cloning.

The patient-derived segment may be obtained by any of molecular cloning or gene method or modifications thereof, amplification, introducing patient sequence acceptor sites, described below, at the ends patient-derived segment to be introduced into vectors, such described as the hepadnavirus expression vector. For example, in a gene amplification method such as corresponding restriction sites to the sites patient-sequence acceptor can be incorporated at the ends of the primers used Similarly, in PCR reaction. molecular cloning method such as cDNA cloning, said restriction sites can be incorporated at the ends of the primers used for first or second strand cDNA synthesis, or in a method

10 C C C C C C C C C

بتستإ

5

25

10

25

30

such as primer-repair of DNA, whether cloned or uncloned DNA, said restriction sites can be incorporated into the primers used for the repair reaction. The patient sequence acceptor sites may also be regions designed to permit homologous recombination or complementary annealing between the patient derived segment and the hepadnavirus expression vector sequence acceptor sites and The patient designed to improve the are patient-derived representation of segments. of vectors having designed patient sequence acceptor sites provide representation patient-derived segments that would underrepresented in one vector alone.

As used herein, "replication capacity" is defined herein is a measure of how well the virus replicates. This may also be referred to as viral fitness. In one embodiment, replication capacity can be measured by evaluating the ability of the virus to replicate in a single round of replication.

As used herein, "control resistance test vector" is defined as a resistance test vector comprising a standard hepadnavirus sequence (for example, HBVayw and an indicator gene.

As used herein, "normalizing" is defined as standardizing the amount of the expression of indicator gene measured relative to the number of viral particles giving rise to the

expression of the indicator gene. For example, normalization is measured by dividing the amount of luciferase activity measured by the number of viral particles measured at the time of infection.

30

"Plasmids" and "vectors" are designated by a lower case p followed by letters and/or numbers. herein The starting plasmids are commercially available, publicly available on an unrestricted basis, or can be constructed plasmids in accord available from published procedures. In addition, equivalent plasmids to those described are known in the art and will be apparent to the ordinarily skilled artisan.

the vectors of the invention Construction of ligation and restriction employs standard techniques which are well understood in the et al., (1987)art (see Ausubel Current Protocols in Molecular Biology, Wilev Interscience or Maniatis et al., (1992)Molecular Cloning: A laboratory Manual, Cold Spring Harbor Laboratory, N.Y.). Isolated sequences, synthesized plasmids, DNA or oligonucleotides are cleaved, tailored, religated in the form desired. The sequences of all DNA constructs incorporating synthetic DNA can be confirmed by DNA sequence analysis (Sanger et al. (1977) Proc. Natl. Acad. Sci. 74, 5463-5467).

30

The development of a method to generate infectious hepadnavirus pseudotyped virions having proteins derived from envelope a foamy enables the development retrovirus in vitro cell based assays for hepadnaviruses, not limited including but to susceptibility and resistance essays, fitness assays, and genotypic assays identify hepadnavirus mutations which confer drug resistance.

The following examples are presented to further illustrate and explain the invention and should not be taken as limiting in any regard.

EXAMPLE 1

Pseudotyping Hepatitis B Virus Using Envelope Proteins Derived from Human Foamy Virus

This example provides a means and methods for generating HBV virions that are capable of primary cell cultures and infecting lines that express established cell the receptor for Human Foamy Virus (HFV). The means and methods provided herein describe the procedures for incorporating HFVproteins into the membrane of HBV infection of target cells that are permissive for HFV infection, i.e. express HFV receptors on the cell surface. HBV virions produced by the method enter the cell by binding and

10

25

30

interacting with the HFV receptor, thereby circumventing the normal HBV entry pathway, which is thought to involve the HBV surface protein (S) and an, as yet, unidentified host cell HBV receptor. It is widely held that the inability of HBV to infect cultured cells is likely to be due to а block(s) at the attachment and/or entry steps. The means and for producing infectious by methods HFV envelope with proteins pseudotyping provided in this example can be adapted to other hepadnaviruses, some of which may serve as useful animal models for HBV disease, for example duck and woodchuck hepadnaviruses. Addition, the means and methods for producing pseudotyping with infectious HBV by proteins can be adapted to envelope pseudotyping HBV and other hepadnaviruses with the envelope proteins of other foamy viruses (spumaviruses), retroviruses, and a variety of enveloped viruses.

The system for the production of HBV particles pseudotyped with HFV envelope proteins and the successful infection of cultured cells involves the following components;

(i) <u>HBV genome expression vector</u>: a DNA vector that comprises the HBV genome and is capable of transient transcription of HBV RNA and HBV protein production following introduction into an appropriate cell line.

- (iii) <u>HFV envelope expression vector</u>: a DNA vector that comprises the HFV envelope gene and is capable of transiently producing HFV envelope proteins following introduction into an appropriate cell line.
- (iv) <u>Packaging host cell</u> or first cell: cells that can support transient expression of HBV genomic and HFV envelope expression vectors.
- (v) <u>Target cell or second cell</u>: cells that express the HFV envelope receptor and are capable of supporting HBV replication once HFV pseudotyped HBV virions have entered the cell via the HFV receptor.
 - HBV genome expression vectors are capable of producing HBV particles following introduction into packaging host cells. HBV gene expression can be regulated by HBV regulatory elements, or by exogenous regulatory elements derived from other sources, e.g.

30

10

25

30

cytomegalovirus immediate-early gene promoter/enhancer (CMV-IE). Ιn а preferred embodiment of this invention, expression of the HBV regulated genome is by the CMV-IE promoter/enhancer. **HBV** genome expression vectors may also contain an indicator gene, such firefly luciferase. Τn this case, the as vectors are referred to as "HBV indicator gene viral vectors" or more generally as "indicator vectors". The indicator viral provides a sensitive and convenient mechanism for measuring the infectivity of target cells following infection by virus produced in host The amount of indicator gene packaging cells. product, i.e. luciferase activity, produced in target cells is a direct measure of a single round of HBV replication. HBV indicator gene vectors can be used to assemble viral "Resistance/fitness test vectors" by replacing specific HBV sequences of the HBV indicator gene viral vector with HBV gene sequences (e.q. P gene reverse transcriptase sequences) from a variety of other sources. Sources may include patient samples harboring drug sensitive or drug resistant strains of HBV (e.g. viruses sensitive or resistant to lamivudine, [3TC]), and molecular clones of HBV that possess defined that contain or lack drug RTsequences resistance associated mutations (M550V).

The HFV envelope expression vector contains the HFV envelope gene region and is used to produce the HFV envelope gene product (gp130env). The

10

25

30

gp130env is a polyprotein that is cleaved in the cytoplasmic membrane compartment by a cellular "furin-like" protease to produce the envelope surface (gp80SU) and transmembrane (qp48TM). Together, SU and TM function in host cell recognition and entry of HFV. The introduction of HFV envelope expression vectors genome vectors along with HBV into packaging cells results in the production of HBV virions bearing HFV envelope proteins in the viral membrane (pseudotyped virus particles). Expression of HFV envelope in host packaging regulated by variety cells can be а regulatory elements including, but not limited to the CMV-IE promoter/enhancer, the HFV or In a preferred embodiment of promoter/enhancer. invention, the HFV envelope expression inserting is assembled by HFV vector envelope gene region into an expression vector that contains the CMV-IE promoter/enhancer (e.g. pCXAS, Petropoulos et al., 1999 Cite Full Ref).

Packaging host cells may include a wide variety of human or mammalian cell lines including, but not kidney to, human embryonic limited (HEK293) and human hepatoma cells (HepG2, Huh7). cell transiently The ideal packaging host produces large numbers of HFV pseudotyped HBV virions following the introduction of HBV genome expression vector and HFV envelope expression vector DNAs.

Target cells may include primary cells and cell lines, and more specifically primary hepatocytes and cell lines of hepatic origin, including but not limited to HepG2 cells and Huh7 cells (ref). The ideal target cell expresses HFV receptor(s) on the cell surface and supports HBV replication steps that are downstream of virus attachment and entry.

5

2,5

30

produce infectious HBV virus particles an HBV genome expression vector plus an HFV envelope is introduced into expression vector host cells. Several days later, HFV packaging pseudotyped HBV particles produced by the host packaging cells are harvested and used cells. Several days after inoculate target inoculation, the infectivity of target cells is introduction of HBV The genome measured. expression vector and HFV envelope expression vector DNAs into host packaging cells can be variety of well-established by a performed but not limited to including, procedures calcium-phosphate-DNA precipitation and Measuring the infectivity of electroporation. target cells by HBV can be performed by a well-established procedures variety of including, but not limited to the detection of HBV antigens (e.g. antibody based Western blot or ELISA detection), or HBV nucleic acids (e.g. RT-PCR, Northern blot, Southern PCR. detection).

10

In a preferred embodiment of this invention, the HBV genome expression vector and the HFV envelope expression vector are regulated by the CMV-IE promoter/enhancer. The HBV genome contains a luciferase indicator gene. The host packaging cell is HEK293. The HBV genome expression vector and the HFV envelope expression vector introduced into host packaging cells calcium-phosphate-DNA precipitation. Five to ten micrograms of each vector DNA preparation are used. After transfection, host packaging incubated for 24-72 hours. Cells plus media are collected and frozen thawed to release cell-associated virions. The centrifuged and filtered the media is filtrate serves as the stock of HFV pseudotyped HBV for infection of host target cells. The target host cell is HepG2 or Huh7. Infected cells are lysed 48-72 hours after infection and luciferase activity is measured in of luciferase activity The amount lysate. detected in infected cells serves as a direct measure of a single round of HBV replication.

Pseudotyping Hepatitis B Virus Using Chimeric Envelope Proteins Derived from Human Foamy Virus and Hepatitis B Virus

5

10

25

30

This example provides a means and methods generating HBV virions that are capable infecting primary cell cultures and established cell lines that express the receptor for Human (HFV). The means Foamy Virus and methods provided herein describe the procedures incorporating HBV/HFV chimeric envelope proteins into the membrane of HBV and the infection of target cells that are permissive for HFV · infection. i.e. express HFV receptors on the cell surface. HBV virions produced by method enter the cell by binding and interacting with the HFV receptor, thereby circumventing the normal HBV entry pathway, which is thought to involve the HBV surface protein (S) and an, yet, unidentified host cell HBV receptor. It is widely held that the inability of HBV to infect cultured cells is likely to be due to a block(s) at the attachment and/or entry steps. Based on this example, it is obvious that the means and for producing infectious HBV methods with HBV/HFV chimeric envelope pseudotyping proteins can be adapted to other hepadnaviruses, some of which may serve as useful animal models for HBV disease, for example duck and woodchuck hepadnaviruses. Based on this example, it also obvious that the means and methods for producing infectious HBV by pseudotyping with HBV/HFV chimeric envelope proteins

adapted to pseudotyping HBV and other hepadnaviruses with chimeric envelope proteins derived from other foamy viruses (spumaviruses), retroviruses, and a variety of enveloped viruses.

10

5

25

- The system for the production of HBV particles pseudotyped with HBV/HFV chimeric envelope the successful infection of proteins and cultured cells may involve the following components;
- HBV genome expression vector: DNA а vector that HBV genome and is capable contains the transient transcription of RNA HBVand protein production following introduction into an appropriate cell line,
- HBV indicator gene viral vector: a DNA vector that contains elements of the HBV genome and an indicator gene, such as firefly luciferase and is capable of transient transcription of an RNA. The RNA contains the signals/elements required for packaging of the RNA into HBV virions and for reverse transcription of the RNA transcript by the HBV polymerase and for the expression of the indicator gene,
- HBV/HFV chimeric envelope expression vector: a DNA vector that contains the sequences coding for a HBV/HFV chimeric envelope gene and is capable of transiently producing the HBV/HFV chimeric envelope proteins following introduction into an appropriate cell line,

<u>Packaging host cells</u>: cells that can support transient expression of HBV genomic and HFV envelope expression vectors,

<u>Target host cells</u>: cells that express the HFV envelope receptor and are capable of supporting HBV replication once HBV particles pseudotyped with the HBV/HFV chimeric envelope have entered the cell via the HFV receptor.

vectors capable HBV genome expression are of HBV particles following their producing introduction into packaging host cells. HBV gene expression can be regulated by HBV regulatory elements, or by exogenous regulatory elements derived from other sources, e.g. the cytomegalovirus immediate-early promoter/enhancer (CMV-IE). Ιn a preferred embodiment of this invention, expression of the is regulated by the CMV-IE HBV genome HBV promoter/enhancer. genome expression vectors may also contain an indicator gene, such firefly luciferase. In this case, vectors are referred to as "HBV indicator gene viral_vectors" (Figure 1). The indicator gene provides a sensitive and convenient mechanism for measuring the infectivity of host target cells following infection by virus produced in The amount of indicator host packaging cells. gene product, i.e. luciferase activity, produced in host target cells is a direct measure of a single round of HBV replication. HBV genome expression vectors and/or HBV indicator used to assemble "HBV viral vectors can be

10

5

TAMONT IN THE STATE OF THE STAT

25

Resistance/fitness test_vectors" (see Figure 2 and Example 3 below). HBV Resistance/fitness test vectors are produced by replacing specific sequences of the HBV genome expression vector or the HBV indicator gene viral vector with HBV gene sequences (e.g. P gene reverse transcriptase sequences) derived from a variety of other sources. Sources may include patient harboring drug sensitive samples resistant strains of HBV (e.g. viruses sensitive to lamivudine, [3TC]), resistant molecular clones of HBV that possess defined RT sequences that contain or lack drug resistance associated mutations (M550V).

The HFV gp130env envelope is a polyprotein that is cleaved in the cytoplasmic membrane compartment by a cellular "furin-like" protease to produce (U208qp) envelope surface the mature and transmembrane (gp48TM). Together, SU function in host cell recognition and entry of The HBV PreS1/PreS2/S gene codes for three proteins depending on the promoter different The three proteins S, M and L contain identical C-terminii and differ in the presence or absence of the PreS1 and/or PreS2 domains (See Figure 3). The HBV/HFV chimeric envelope expression vector contains sequences that encode a chimeric protein which contains amino acids derived from the entire S domain and additional PreS2 sequences of the HBV and covalently linked to amino acids of the HFV SU (qp80) envelope gene region. In a preferred

EXAMPLE 4

Methods for Identifying Genetic Mutations Associated with Changes in HBV Drug Susceptibility And/or Replicative Capacity.

This example provides а means and method for identifying mutations in reverse transcriptase alter HBV susceptibility drug replication fitness. The means and methods for identifying mutations that alter HBV susceptibility and/or replication fitness can be adapted to other steps in the HBV replication cycle, including, but not limited to formation, virus assembly, and virus egress. This example also provides a means and method for quantifying the affect that specific reverse trascriptase mutations have on susceptibility and/or replicative capacity. means and method for quantifying the affect that specfic reverse transcriptase mutations have on drug susceptibility and/or replicative capacity

5

10

25

can be adapted to mutations in other viral genes involved in HBV replication, including the ${\tt C}$ and ${\tt X}$ genes.

5

25

30

HBV Resistance/fitness test vectors are constructed referenced in Example 1. described and as Resistance/fitness test vectors derived from derived from the patient samples or clones pools, resistance/fitness vector test resistance/fitness test vectors engineered site directed mutagenesis to contain specific mutations, are tested in drug susceptibility and fitness assays to determine accurately drug susceptibility and quantitatively the fitness compared to wellrelative characterized reference standard. In another invention, the drug embodiment of the susceptibility and/or fitness of the patient virus is compared to viruses collected from the time points, at different patient same example prior to initiating therapy, before or after changes in drug treatment, or before or after changes in virologic (RNA copy number), T-cells), or clinical immunologic (CD4 (opportunistic infection) indicators of disease progression. The results of patient samples can be further examined for changes in reverse activity associated with transcriptase the observed changes in drug susceptibility and/or relative fitness.

10

25

30

Reverse transcriptase activity can be measured by any number widely used assay procedures, of including but limited to homopolymeric not extension oligo dT:poly rC) (e.g. conventional or real time PCR based on molecular (reference Kramer?) or 5'exonuclease beacons activity (Lie and Petropoulos, 1996). In one embodiment, virion associated reverse transcriptase activity is measured using a quantitative PCR assay that detects exonuclease activity associated with thermostable DNA polymerases. In one embodiment of the invention, the HBV RT activity of the patient virus is compared to the HBV RT activity of a reference virus (i.e. "wildtype") that has not been exposed to reverse transcriptase inhibitors antiviral drugs. Ιn another or other embodiment, the HBV RT activity is compared the HBV RT activity of viruses collected from the at different time points, for same patient example prior to initiating therapy, before or after changes in drug treatment, or before or after changes in virologic (RNA copy number), clinical immunologic (CD4 T-cells), or (opportunistic infection) indicators of disease progression.

Genotypic Analysis of Patient HBV Samples

Resistance/fitness test vector DNAs, either pools or individual clones which make up the pools, are analyzed by any number of widely practiced genotyping methods (e.g. nucleic acid sequencing, differential probe hybridization,

5

25

30

oligonucleotide array hybridization). embodiment of the invention, patient HBV sample sequences determined using are viral purification, RT/PCR and dideoxynucleotide chain terminator sequencing. The sequence that determined is compared to reference sequences present in the database, or is compared to a sample from the patient prior to initiation of therapy, if available. The genotype is examined sequences that are different from pre-treatment sequence and reference or change correlated to the observed drug susceptibility and/or replicative capacity.

Drug Susceptibility and Replicative Fitness Analysis of Site Directed Mutants

Genotypic changes that are observed to correlate with in HBV drug susceptibility changes evaluated. by fitness are replicative resistance/fitness test vectors constructing containing the specific mutation on a defined background derived from wellgenetic а susceptible virus (i.e. characterized, drug Mutations may be incorporated "wildtype"). alone and/or in combination with other mutations thought modulate the drug that are to susceptibility and/or fitness of а virus. introduced into the Mutations are resistance/fitness test vectors through any of site-directed for known methods widelv mutagenesis. Ιn one embodiment of this for mega-primer PCR method invention the

10

1985571 15E1

mutagenesis is used. site-directed Resistance/fitness test vectors containing specific mutation, or group of mutations, susceptibility the drug and/or tested using fitness assays described in Example 3. fitness of the mutant virus is compared to that the reference virus lacking the specific mutation(s). Observed changes in drug susceptibility and/or fitness are attributed to specific mutations introduced into the In a related embodiment resistance test vector. the invention, resistance/fitness vectors containing site directed mutations in reverse transcriptase that result in amino acid substitutions at position 550 (M550V, M550I) are constructed and tested for drug susceptibility and/or fitness. The fitness results enable the specific between reverse correlation substituions acid transcriptase amino changes in drug susceptibility and/or fitness.
